A Review of Monolaurin and Lauric Acid

Natural Virucidal and Bactericidal Agents

Shari Lieberman, Ph.D., C.N.S., F.A.C.N., Mary G. Enig, Ph.D., C.N.S., M.A.C.N., and Harry G. Preuss, M.D., C.N.S., M.A.C.N.

Antibiotic resistance has become a worldwide problem for treating infections caused by numerous organisms. Safe, effective antimicrobials that are not easily subject to resistance are desperately needed. The Food and Drug Administration (FDA) states on its website: “Disease-causing microbes that have become resistant to drug therapy are an increasing public health problem. Tuberculosis, gonorrhea, malaria, and childhood ear infections are just a few of the diseases that have become hard to treat with antibiotic drugs.”1 The FDA website also notes:

- Though food-producing animals are given antibiotic drugs for important therapeutic, disease prevention, or production reasons, these drugs can cause microbes to become resistant to drugs used to treat human illness, ultimately making some human sicknesses harder to treat.
- About 70 percent of bacteria that cause infections in hospitals are resistant to at least one of the drugs most commonly used to treat infections.
- Some organisms are resistant to all approved antibiotics and must be treated with experimental and potentially toxic drugs.
- Some research has shown that antibiotics are given to patients more often than guidelines set by federal and other health care organizations recommend. For example, patients sometimes ask their doctors for antibiotics for a cold, cough, or the flu, all of which are viral and do not respond to antibiotics. Also, patients who are prescribed antibiotics but do not take the full dosing regimen can contribute to resistance.
- Unless antibiotic resistance problems are detected as they emerge, and actions are taken to contain them, the world could be faced with previously treatable diseases that have again become untreatable, as in the days before antibiotics were developed.

Not only bacteria develop antibiotic resistance—viruses develop resistance as well. Accordingly, the need for safe, effective antivirals is also becoming paramount. For example, virucidal resistance has occurred in Herpes simplex virus type 1 as a result of acyclovir use.2

In a site-directed study of mutagenesis, researchers investigated the role of six mutations of Herpes simplex virus type 1 thymidine kinase (TK) gene in the acquisition of resistance to acyclovir (ACV).2 TK activity was not impaired by substitutions located at codons 17, 161, and 374, and these mutations were thus related to TK gene polymorphism. Mutations His105Pro, Leu364Pro, and Asp162Ala lead to the loss of TK activity that could result in ACV-resistance. However, there are very limited antiviral treatments in conventional medicine against the vast majority of viruses that infect humans.

Monolaurin

Monolaurin, a monoester formed from lauric acid (medium-chain fatty acids), has profound antiviral and antibacterial activity. Recognition of the antiviral activity of the monoglyceride of lauric acid (monolaurin) has been reported since 1966. A large body of the research can be credited to Jon J. Kabara, B.S., M.S., Ph.D., a professor emeritus of Michigan State University in East Lansing.3 His early pioneer work focused on the virucidal effects of monolaurin (Lauricidin,® Med-Chem Laboratories, Inc., Galena, Illinois) on enveloped RNA and DNA viruses. This work continues to be investigated by numerous researchers because of the potential benefits related to food preservation.

A recent study that investigated the sanitizing effects of monolaurin in a laboratory scale system, partially reproduced dairy plant conditions. The study focused on the effectiveness of chlorine and alternative sanitizers for reducing the number of viable bacteria attached to stainless-steel surfaces.4 Bacteria-contaminated stainless-steel tubes in a continuous-flow reactor were exposed to a standard clean-in-place regimen (water rinse, 1 percent sodium hydroxide at 70°C for 10 minutes, a second water rinse, 0.8 percent nitric acid at 70°C for 10 minutes, and a third water rinse) followed by exposure to either chlorine (200 ppm) or combinations of nisin (500 ppm), Lauricidin (100 ppm), and the lactoperoxidase system (LPS) (200 ppm) for 10 minutes or 2, 4, 8, 18, or 24 hours.4 There was significant variation in the effectiveness of the alkaline-acid wash steps in reducing cell numbers (log reduction between 0 and 2). Following a 10-minute treatment, none of the...
Monolaurin Chemistry in the Human Body

Coconut oil and certain coconut products contain approximately 50 percent lauric acid and approximately 6–7 percent capric acid. The question arises frequently whether ingestion of lauric acid can lead to significant endogenous production of monolaurin. There do not appear to be any clear data concerning how much monolaurin is actually formed from lauric acid in the human body. Nevertheless, there is evidence that some is formed. Lauric acid is the main antiviral and antibacterial substance found in human breast milk.

Compared to other medium-chain triglycerides such as caprylic acid (C8), capric acid (C10), or myristic acid (C14), monolaurin is many times more biologically active than lauric acid in killing viruses and bacteria, leading to the interesting question concerning the conversion rate in the human body. Unlike these medium-chain fatty acids, diglycerides and triglycerides are active against microorganisms.

Research has suggested that monolaurin exerts virucidal and bactericidal effects by solubilizing the lipids and phospholipids in the envelope of the pathogen causing the disintegration of its envelope. Recent evidence has also indicated that the antimicrobial effect is related to its interference with signal transduction in cell replication.

Bactericidal Effects

Other studies, in addition to the abovementioned one with the milk-processing equipment, indicate that monolaurin has antibacterial activity. This monoeaster has been shown to be effective against both susceptible and antibiotic-resistant Staphylococcus aureus.

Generally, monolaurin is more effective against gram-positive bacteria such as staphylococcus and streptococcus. In a study conducted by Preuss et al., monolaurin was shown to be bactericidal to S. aureus and Mycobacterium terrae but not Escherichia coli and Klebsiella pneumoniae, which are both gram-negative, confirming prior work on monolaurin, and was shown to be static to a variant of the virulent anthrax pathogen, Bacillus anthracis Sterne.

Monolaurin also inhibits production of staphylococcal toxic shock toxin-1 effectively. The monoester is effective against cytomegalovirus and the expression of virulence factors including protein A, alpha-hemolysin, B-lactamase, and the induction of vancomycin resistance in Enterococcus faecalis. Monolaurin has also been shown to inactivate Listeria monocytogenes, Streptococcus agalactiae, and Groups A, F, and G streptococci. (See Table 1.)

Unlike conventional antibiotics, monolaurin does not appear to have an adverse effect on gut probacteria.

Antifungal Effects

In addition, a number of fungi, yeasts, and protozoa are reported to be inactivated or killed by monolaurin. These fungi include several species of ringworm. Candida albicans and the protozoan parasite Giardia lamblia were both reported to be killed by monolaurin.

Virucidal Effects

Some of the viruses inactivated to some extent by monolaurin include HIV, measles, Herpes simplex-1, vesicular stomatitis, visna virus, and cytomegalovirus. Results of an extremely promising trial with HIV-positive male and female patients compared the effectiveness of monolaurin at two doses (2.4 g versus 7.2 g) with 50 mL of coconut oil in 15 patients. The objective was to document if the patients’ viral loads could be lowered by any of these treatments.

The patients were divided into 3 groups of 5 patients. They were seen daily with laboratory values determined at the beginning of the study and after 3 months and 6 months. At the onset of the trial the viral load of the patients measured by PCR, ranged from 1.96 x 10^3 to 1190.0 x 10^3 copies.

One (1) male had a viral count too low to measure and was not included in the final statistics. Seven (7) of the remaining 14 patients had reduced loads at 3 months (2 males and 5 females), and 8 patients of the 14 patients had reduced viral loads at 6 months.

However, the reduction was significant in only 3 patients (2 males and 1 female). Two (2) of these 3 patients were in the coconut-oil group and 1 was in the lower dose (2.4 g) monolaurin group.

Significant funding is being sought in order to carry out a larger investigation. It is significant that several of the viruses inactivating protein A, alpha-hemolysin, B-lactamase, and the induction of vancomycin resistance in Enterococcus faecalis.
Virology: Monolaurin, a Naturally Occurring Antimicrobial Agent

Monolaurin is a naturally occurring antimicrobial agent that is produced by the metabolism of lauric acid, a fatty acid found in coconut oil. This article discusses the role of monolaurin in the human body, particularly in the context of viral infections and immune function.

for more than a decade with excellent results. Given its broad-spectrum activity, it has been used along with glycyrrhizin successfully to treat numerous cases of chronic fatigue syndrome, CMV infection, Epstein-Barr virus, Herpes simplex-1 and -2, fungal infections, and C. albicans—all common conditions that are seen in an integrative practice. SL has not personally used it for G. lamblia, which has become resistant to metronidazole and other antiparasite drugs.

Despite the unanswered question regarding whether substantial amounts of lauric acid are metabolized to monolaurin, it is important to note that lauric acid is also effective against, at least to some extent, the microorganisms listed in Tables 1 and 2. Lauric acid produces greater activity against microorganisms than caprylic acid, capric acid, or myristic acid, all of which are present in coconut oil. Given that coconut oil provides approximately 50 percent lauric acid, a substantial amount of this bactericidal and virucidal fatty acid can be obtained from consuming coconut fat in pure coconut oil, and in many foods and products. (See Tables 3 and 4; Table 4 suggests three coconut-based products.)

In addition, it is important to note that lauric acid appears to have immune-boosting properties as evidenced by feeding coconut oil to laboratory animals in whom the expected immune-factor responses (inhibition of interleukin-1) to endotoxin were induced via corn-oil feeding. Ingesting monolaurin on a daily basis may be an inexpensive way to both treat and prevent infection from microorganisms. This would be especially valuable, given that we are now living under a constant threat of bioterrorism.

The results of the small study examining the effects of monolaurin versus coconut oil were compelling. It is a shame that a larger study has not been funded thus far. Despite the small number of patients in the study, both coconut oil and the lower dose of monolaurin (2.4 g) were both effective in significantly lowering the viral load for several patients. Perhaps a large amount of coconut oil may have a similar effect to a smaller dose of monolaurin. Because monolaurin is more active than lauric acid, a smaller amount is needed for its antimicrobial effects.

**Conclusions**

Monolaurin has Generally Recognized As Safe (GRAS) status and is considered to be nontoxic. It is effective against many microorganisms and can be taken on a daily basis, given that evidence suggests it does not create antiviral or antibacterial resistance.

The general recommended adult dose of monolaurin is 1–3 g. Higher amounts can be used to achieve desired results if necessary. It is safe for children (ages 3–10) with the recommended dose being smaller—30 mg, one to three times per day. Monolaurin is available as minipellets that should be swallowed and not chewed.

Coconut oil, coconut cream, grated coconut, and other products listed in Tables 3 and 4 are excellent sources of lauric acid and the other medium-chain fatty acids as well. Coconut oil provides mostly medium-chain triglycerides that are rapidly absorbed and transported to the mitochondria where they are utilized for fuel and may be less likely to be stored as body fat.

Coconut oil does not have a deleterious effect on cholesterol or other blood lipids. In fact, it may raise high-density lipoprotein cholesterol. Coconut oil is rich in “good” saturated fatty acids that conserve the elongated omega-3 fatty acid. Animal studies have shown that some omega-3 fatty acids can be formed as a result of ingestion of coconut oil. Coconut oil does not contain trans fatty acids that have deleterious effects on blood lipids and insulin binding.

Both monolaurin and coconut oil are excellent choices for combating a host of microorganisms—both therapeutically and preventively. More human studies are needed to elucidate the best therapeutic dose of monolaurin and coconut for addressing specific microorganisms and conditions.

It is also important to quantify how much monolaurin is metabolized from a specific quantity of coconut oil. Finally, it is equally important to compare large doses of coconut oil to specific doses of monolaurin for their antimicrobial action as was done in the HIV study population. Dietary supplements such as monolaurin may be unavailable to some populations while coconut oil may be a less-costly alternative.
